Descriptive Statistical Analysis

Sales Performance KPIs

- The total revenue is about 21.78 million TRY, which shows that the business is doing very well overall.
- There were 17,049 orders processed, which shows that customers are always using the platform.
- The average order value (AOV) of 1,277 TRY shows that customers usually buy things that are worth a lot of money.
- The average customer rating of 3 shows that customers are somewhat satisfied, which means that most customers are happy but there is still room for improvement.
- The average delivery time of 6.5 days shows that logistics are working at a moderate level, which could affect how happy customers are.
- The 38% discount penetration rate shows that discounts are a big part of making sales.

- Also, 88.2% of all orders come from repeat customers, which shows that customers are very loyal and stay with the company.
- The fact that only 11.8% of customers are new, though, suggests that the company may need to work on its customer acquisition strategies.

Sales Trend and Seasonality Analysis

- The analysis of sales trends shows that revenue changes from month to month, which means that there are seasonal patterns. Some months, like December, October, and July, bring in greater revenue. This is probably because of sales, holiday seasons, or higher demand from shoppers during busy times. On the other hand, months that don't do as well, like January, February, and March, may be affected by less marketing or less consumer spending.

- The seasonal index shows which months have better or worse performance than average, which helps the business plan its inventory and marketing strategies better. Months with an index higher than 1 show better-than-average performance and should be the focus of more marketing efforts.

- The analysis of the day of the week shows that customers act differently on different days. Usually, there are more orders on weekdays because people shop regularly. On weekends, though, people may spend more per order because they have more time to look around and make smart purchases. These ideas can help you make the most of your marketing campaigns and the timing of your promotions.

Customer and Demographic Analysis

- The analysis shows that returning clients make much greater contributions towards the generation of revenues than new clients. Returning clients spend more money, engage better, and have higher satisfaction rates. Thus, they are very valuable for the business.

- According to the city level analysis, there are cities where high revenues are observed because of high order quantities, and there are cities that have high order values even though there are not too many orders. Thus, it is important to use location-specific marketing activities to maximize revenues.

- Analysis according to demographic factors such as age groups and gender reveals some distinctions between purchasing habits and preferences of different target markets, including their interest in certain products and their expenditure patterns. It is possible to use this information when planning marketing activities and developing the product line.

- Using RFM-based segmentation again proves that “Champions” and “Loyal Customers” segments make the greatest contribution to total revenues, whereas “At Risk” and “Lost” segments contribute relatively less to revenues.

Digital Behavior and Device Analysis

- Analysis of viewed pages It proves that customers' spending amounts rise in proportion to the number of visited pages. Hence, promoting user interaction within the platform results in better performance.

- Preferences related to payment method vary depending on the device used. Customers operating from smartphones prefer rapid transactions, while desktop users prefer traditional means such as credit cards. This highlights the importance of optimizing the payment experience across devices.

Delivery Performance and Customer Satisfaction

- Efficient delivery is critical for customer satisfaction. As shown by the analysis, products with shorter delivery times get higher customer evaluations, indicating a significant connection between efficient logistics operations and a good customer experience. Based on the analysis of delivery speed segments, it was found that:
  (1-3days) delivery gets the highest ratings
  (4-days) delivery gets medium satisfaction levels
  (8+-days) delivery gets low customer evaluations
- It was noted that there were more return customers within the fast delivery segment, which could be an indication that delivery speed affects customer retention rates positively. According to the discount analysis, it can be concluded that although discounts affect sales, they cannot be said to affect customer satisfaction to a great degree.
